

VOLT - LOCAL ENERGY LEDGER

7-Minute Shark Tank Pitch + Demo + Judge Q&A

A flexible, stage-ready script for three presenters. Replace A, B and C with your names before printing.

THE ONE-SENTENCE IDEA

Volt models neighbours exchanging surplus rooftop-solar energy at a fair community rate, while every settlement is recorded in a tamper-evident ledger.

Speaker assignment

A - Persuasive lead	B - Technical lead	C - Simple explainer
Hook, problem, value, closing Target: 2 min 10 sec	Website demo, specs, proof Target: 2 min 15 sec	Three steps, model, tamper result Target: 1 min 25 sec

Exact run of show

CLOCK	OWNER	SECTION	LENGTH
0:00-0:30	A	Hook	0:30
0:30-1:05	A	Problem and price gap	0:35
1:05-1:45	C	Generate - Log - Settle	0:40
1:45-2:55	B	Website and neighbourhood demo	1:10
2:55-3:40	C	Physical model + tamper result	0:45
3:40-4:30	A	Value and business logic	0:50
4:30-5:35	B	Technical credibility and limits	1:05
5:35-5:50	A	Close	0:15
5:50-7:00	All	Judge Q&A	1:10

Timing rule: B keeps a phone timer where only the team can see it. If the clock reaches 5:20, B skips the optional flex line and moves straight to A's closing.

SCRIPT / PART 1

Open with the problem, then make the idea simple

Words in italics are optional. Natural pauses and one extra sentence are safe; keep each handoff line unchanged.

0:00-0:30 A - Persuasive lead	
DO / SHOW	Stand centre. Do not touch the screen yet. Pause after the question.
SAY	Good morning, judges. Imagine two homes on the same street. One roof is producing extra solar power, while the home next door needs electricity. Why should the first family sell that energy cheaply to the grid, only for the second family to buy it back at a much higher price? Volt helps the street share that value.
FLEX LINE	<i>If the room feels responsive: 'The energy travels only a short distance. We believe the benefit should stay just as local.'</i>
0:30-1:05 A - Persuasive lead	
DO / SHOW	Show the landing-page price comparison. Point once to each number.
SAY	Our prototype uses the comparison shown here: the grid buys surplus at about ₹3 per unit and sells electricity at about ₹8. Volt models a community rate near ₹5.50, plus a small ₹0.40 network fee. In this example, the solar owner earns ₹2.50 more per unit, the neighbour saves ₹2.10, and the network can sustain itself.
FLEX LINE	<i>Say 'illustrative rate' if a judge asks whether this is an official tariff. Do not call it a guaranteed saving.</i>
1:05-1:45 C - Simple explainer	
DO / SHOW	Take one small step forward. Use three fingers. Speak slowly.
SAY	Volt works in just three steps. First, Generate: a rooftop makes more solar energy than that home needs. Second, Log: the extra energy is recorded clearly. Third, Settle: a nearby home receives the local energy, and the record is updated. So the simple idea is: local energy, a fairer rate, and a record people can check. Now B will show you our working website.
FLEX LINE	<i>Memory rescue: 'Generate. Log. Settle. Local energy with a record people can trust.'</i>

C'S SAFETY RULE

C does not explain code, law, meter hardware, or detailed pricing. If interrupted with a hard question: 'B can explain the technical side of that,' then look at B.

SCRIPT / PART 2

Demonstrate the system without getting trapped by the screen

The spoken story matters more than perfect clicking. If one control fails, continue with the visible page and describe the intended result honestly.

1:45-2:55 B - Technical lead	
DO / SHOW	Open the ledger. Show the 10-home map, household cards, day selector, then the chain. Do not open every panel.
SAY	This is a synthetic neighbourhood of ten households in Nolambur, Chennai. Some homes are producers with surplus rooftop solar; others are consumers. The map shows local energy flow, and the household cards show generation, demand, imports, exports and balances. We can switch between a sunny weekday, cloudy day, weekend and heatwave. The same inputs always replay the same result, so the demonstration is repeatable rather than random. Every trade is then added to this ledger with its time, seller, buyer, energy and credit.
FLEX LINE	<i>If ahead of time: 'The dashboard also shows carbon avoided, grid dependence, neighbourhood autonomy and fairness.'</i>

2:55-3:15 C - Simple explainer	
DO / SHOW	Point to the physical model. Use the version below that matches what actually works.
SAY	Our physical model makes the same idea visible: one home has extra solar energy and another home needs it. The lights or indicators show energy moving locally, while the website keeps the detailed record.
FLEX LINE	<i>If the model is not fully working: 'This model represents the planned energy flow; the website is the working simulation.' Never claim that it measures real electricity unless it truly does.</i>

3:15-3:40 C - Simple explainer	
DO / SHOW	B runs the tamper test while C speaks. C points to the failed rows and 'INTEGRITY VOID'.
SAY	The most important part is trust. When we change even one past energy value, that record and every record after it fail verification. The screen says INTEGRITY VOID, and settlement stops. When the original value is restored, the chain verifies again. So the system does not pretend an edited record is valid.
FLEX LINE	<i>Memory rescue: 'Change one old value, the chain breaks, and settlement stops.'</i>

IF THE TAMPER CLICK FAILS

B says: 'The intended result is already built into the ledger: changing one old value invalidates that row and every later row.' Do not keep clicking. Move on within five seconds.

SCRIPT / PART 3

Show why it matters, prove credibility, and close

Keep the tone confident but honest: Volt is a tested synthetic prototype, not yet a meter-backed billing product.

3:40-4:30 A - Persuasive lead	
DO / SHOW	Return to centre. Let the demo remain visible behind you.
SAY	Volt creates value for all three sides. The solar owner can receive more than the basic export price. The neighbour can pay less than the retail example. And the small network fee gives the platform a simple revenue path. Beyond money, the dashboard shows how much demand is met without the grid, the carbon avoided by local trading, and whether the benefit is distributed fairly. We are not only asking, 'Did energy move?' We are also asking, 'Was the outcome useful and fair?'
FLEX LINE	<i>If judges look rushed, end after 'simple revenue path' and hand over.</i>

4:30-5:35 B - Technical lead	
DO / SHOW	Show the hash-chain or proof-inspector panel. Keep the explanation at judge level.
SAY	Technically, Volt uses a SHA-256 hash chain. Each ledger entry is sealed using its own contents and the previous entry's seal. If an old entry changes, the seals no longer match. The simulation is deterministic: it models solar and demand by time of day, household and weather scenario, without random results changing between demonstrations. The project can also export the ledger as CSV or PDF, and the larger system supports organisations, roles, simulation runs, immutable settlements and correction entries. One important limit: today's demonstration is synthetic. It is not connected to real smart meters and it does not move real money. The next step is a controlled pilot with approved metering and regulatory partners.
FLEX LINE	<i>Only if asked: the website uses React and TypeScript; the server uses an API, MongoDB and a separate simulation worker.</i>

5:35-5:50 A - Persuasive lead	
DO / SHOW	All three stand in one line. Finish looking at the judges, not the screen.
SAY	Volt turns rooftop surplus into neighbourhood value - fairer for families, visible to the community, and difficult to alter silently. We are Team Volt, and we are ready for your questions.
FLEX LINE	<i>Short emergency close: 'Volt keeps local energy value local - fairly and transparently. Thank you.'</i>

AT 5:50

Stop presenting even if you skipped a line. A says, 'We are ready for your questions.' This protects the full 1 minute 10 seconds reserved for judge Q&A.

5:50-7:00 / JUDGE Q&A;

Short answers that stay truthful

A answers business and impact. B answers technology and feasibility. C answers only the three-step idea or the model. Keep each answer under 20 seconds, then stop.

LIKELY QUESTION	WHO	ANSWER
What exactly is new here?	A	Volt combines a local community-rate model with a visible, tamper-evident settlement record. It also shows autonomy, carbon impact and fairness, not only the energy transfer.
Is this blockchain?	B	It is a SHA-256 hash chain, not a public blockchain. That makes changes detectable, but there is no distributed consensus in this prototype. We describe it as tamper-evident, not tamper-proof.
Does it use real electricity data?	B	Not yet. The current neighbourhood and outcomes are synthetic and repeatable. A real pilot would need approved smart-meter data, consent and utility or regulatory integration.
How do you earn money?	A	The website models a small network fee of ₹0.40 per unit. The exact commercial rate would need validation in a pilot and must fit local rules.
Why would both homes join?	A	In our illustrative comparison, the seller receives more than the grid export price and the buyer pays less than the retail price. Both also get a record they can inspect.
What happens if someone edits a transaction?	C	The changed entry and every later entry fail verification, the ledger shows INTEGRITY VOID, and settlement stops until the original data is restored.
Can corrections be made?	B	History is not secretly rewritten. In the full design, an authorised correction is added as a new adjustment event, so the original evidence remains visible.
What if it is cloudy or demand changes?	C	We can switch the demonstration between sunny, cloudy, weekend and heatwave scenarios. The household generation and demand update for that scenario.
What is your next step?	A	First, finish and test the physical demonstration. Then run a small controlled pilot using approved meter inputs, validate the pricing, and work with the required energy partners before any real settlement.
How is this scalable?	B	The software already separates organisations, roles, simulations and settlement history. Scaling beyond a prototype would mainly require reliable meter integration, operations and regulatory approval.

FINAL REHEARSAL PAGE

Make tomorrow feel controlled

Run the pitch twice tonight and once tomorrow. Do not attempt major new features before presenting.

60-second setup checklist

- ☐ Open the landing page and ledger before your turn; keep both ready.
- ☐ Choose Sunny Weekday and make sure the ledger already contains entries.
- ☐ Test the tamper action once, then restore the original value.
- ☐ Put the physical model in its starting state and decide who touches it.
- ☐ Keep an offline screenshot or the existing project screenshots ready as backup.
- ☐ Turn off notifications; connect power; set browser zoom so judges can read the screen.
- ☐ Write your three names over A, B and C. B starts the hidden timer at A's first word.

Three rules on stage

1	Do not memorise every word. Memorise the first line, the handoffs and the final line.
2	Never call the data live or real. Say synthetic demonstration, simulated neighbourhood or illustrative rate.
3	If something fails, explain what should happen once, then continue. Confidence is better than repeated clicking.

Pocket memory cards

A / PERSUADE	B / PROVE	C / SIMPLIFY
Two homes, one unfair gap. ₹3 → ₹8 vs community rate. Value: seller, buyer, network. Close: fair, visible, hard to alter.	10 synthetic homes. Four day types; repeatable model. SHA-256 links each entry. Honest limit: no real meters or money.	Generate. Log. Settle. Change old value → chain fails → settlement stops.

FINAL TEAM LINE

A: 'We are Team Volt.' All three: 'Thank you.'

Source basis: Volt repository README, CONTEXT.md, landing-page copy, simulation logic, ledger/tamper flow, metrics, proof inspector and system architecture. No hardware capability was invented; the physical-model line is deliberately conditional.
